ENCODING, NUMBER REPRESENTATIONS IN COMPUTING, PART 1.

Lecture 3.

Encoding

- Generally used numeral systems:
 - binary,/base-2, e.g: 00011101
 - each digit is referred to as a bit,
 - used internally by almost all modern computers and computer-based devices,
 - it is a straightforward implementation in digital electronic circuitry using logical gates,
 - decimal/base10/denary, e.g: 156
 - most widely used,
 - fractional part can be:
 - finite,
 - infinite (or non terminating)
 - repeating sequence of digits
 - irrational numbers have infinite (non terminating) decimal representations,
 - irrational number is a real number, that cannot be expressed as a ratio of integers, e.g. $\pi=3.14159\dots\dots$
 - if we would like to use it for computing, we have to convert it – division/multiplication algorithms

Encoding

- hexadecimal/base-16/hex, e.g: 1BE45A
 - it uses sixteen distinct symbols 0...9,A...F,
 - widely used by computer system designers and programmers
- General form of numbers:
 - $A \stackrel{\text{def}}{=} (\pm a_{-m} a_{-m+1} a_{-m+2} \dots a_{-1} a_0, a_1 a_2 \dots a_n)$, where
 - $a_{-m}, a_{-m+1}, \dots, a_{-1} a_0, a_1, \dots, a_n$ are the values of the digits in each local value
 - if the base of the numeral system is r (radix), the number A can be expressed as:
 - $A = \pm \sum_{i=-m}^n a_i r^{-i}$, where $0 \leq a_i < r$, for $\forall i$
 - e.g: $A=7346$
 - $B_{10} = 7346_{10} = 7 * 10^3 + 3 * 10^2 + 4 * 10^1 + 6 * 10^0 = 7000 + 300 + 40 + 6 = 7346_{10}$,
 - $B_8 = 7346_8 = 7 * 8^3 + 3 * 8^2 + 4 * 8^1 + 6 * 8^0 = 3584 + 192 + 32 + 6 = 3814_{10}$,

Encoding

- fixed-point representation:
 - $A = \pm a_{-m} a_{-m+1} a_{-m+2} \dots a_{-1} a_0, a_1 a_2 \dots a_n,$
 - where the integer part of the number is located to the left from the radix point, and the fractional part is located to the right from the radix point,
 - it is generally used to represent numbers with less digits,
- floating-point representation:
 - $A = \pm m * r^{\pm k},$ where $r^{-1} \leq |m| < r^0,$
 - m= mantissa (significand),
 - k=characteristic,
 - r=radix (base)
 - e.g: $-0.999 * 10^{+41}, r=10$
 - every number can be represented in this form!
 - nowadays, r is equal to 2 or 16 in modern computers!

Encoding

- Encoding: it is needed to convert an information into an appropriate form,
 - appropriate form: favorable form to data processing,
- Generally used encoding systems:
 - for numbers:
 - pure binary code,
 - complement code,
 - inverse binary code,
 - binary-coded decimal – BCD,
 - Stibitz code,
 - Gray code,
 - etc...

Encoding

- for characters:
 - telex-code:
 - started in the 1930's, it was a point-to point teleprinter system, it was last used in the United Kingdom in 2008
 - used 5 digits, worked with number-character changing characters

e.g. message: 3/x + 2 expression

1. number changer	11011
2. 3	00001
3. /- slash → "number"	11101
4. character changer	11111
5. x → "letter"	11101
6. number changer	11011
7. +	10001
8. 2	10011

the same code, with different meaning

Telestar 12x

<http://www.cryptomuseum.com/telex/telefunken/telestar/index.htm>

Encoding

- ASCII code:

- American Standard Code for International Interchange,
- earliest version: 7 digits + 1 specified bit,
- $2^7=128$ code words, 7. digit: parity bit, contained numbers from 0 to 9, lower case letters from a to z, uppercase letters from A to Z, punctuation symbols, control codes, space...

source: <http://www.asciitable.com/>

- Code page 1252:

- it is a compatible subset of ISO 8859-1 with extra characters,
- this is the standard character encoding of Western European language versions of Microsoft Windows, including English versions

Encoding

- UNICODE – ISO/IEC 10464:
 - most recent version: Unicode 11.0, contains 137439 characters, covering 146 modern and historic scripts ☺
 - 16 digits in 17 plains, in every plan 65535 code words,
 - 0. plain: Basic Multilingual Plane (Latin-1),
 - 1. plain. Supplementary Multilingual Plane,
 - 2. plain: Supplementary Ideographic Plane,
 - 3...13. plains: unassigned,
 - 14. plain: Supplementary Special Purpose Plane,
 - 15, 16. plains: Supplementary Private Use Area
 - $17 \cdot 2^{16} = 1114112$ pieces of characters (possibility)

http://mkweb.bcgsc.ca/tuple/encode/?color_charts

Binary Encoding

- Fixed-point arithmetic
 - the radix point can be:
 - before the first data bit,
 - after the first data bit,
 - between those,
 - for real fractional numbers, range: $-1 \leq N \leq 1 - 2^{-n}$, *precision*: 2^{-n}
 - for integers (commonly used), range: $-2^n \leq N \leq 2^n - 1$, *precision*: 1
 - for other fractional numbers, range: $-2^m \leq N \leq 2^m - 2^{m-n}$, *precision*: 2^{m-n}
 - the signed bit is the first bit (usually):
 - it is 0, if the number is positive,
 - it is 1, if the number is negative

Binary Encoding

- Negative numbers in fixed-point arithmetic?

- real numbers not exist in the registers!
- the integers are represented in 2's complement code!
 - with the aim of this method, the subtraction may originate in summation

- $$N_{2c} = \begin{cases} N, & \text{if } N \geq 0 \\ 2^k - |N|, & \text{if } N < 0, \text{ where } k = \text{number of the digits (sign + useful digits)} \end{cases}$$

- e.g, if k=8:

- 65 → 01000001
- -65 → 10111111 (256-65 = 191)

Binary Operations

- Addition in 2's complement code:
 - requisite: $A_{2c} + B_{2c} = (A+B)_{2c}$
 - **instead of subtraction, we have to realize addition in the case of the complement coded numbers!**
 - Case 1:
 - $A > 0$ and $B > 0$ and $A > B$
 - in this case: $A_{2c} = A_b$ and $B_{2c} = B_b$
 - then: $A_{2c} + B_{2c} = A_b + B_b = (A+B)_{2c}$

Binary Operations

- Case 1, e.g:
 - $A = 17, B = 9, k = 8$
 - in this case: $A_{2c} = A_b = 00010001$ and $B_{2c} = B_b = 00001001$, if $k = 8$
 - then: $A_{2c} + B_{2c} = A_b + B_b = (A + B)_{2c} \equiv 26 = 00011010$

CY	sign	useful bits	remarks
0	0	0010001	A_b (17)
0	0	0001001	B_b (9)
0	0	0011010	sum (26)

- CY = carry

Binary Operations

- Case 1, - problem, the sum is bigger, then the number range, e.g:
 - $A = 90, B = 56, k = 8$
 - in this case: $A_{2c} = A_b = 01011010$ and $B_{2c} = B_b = 00111000$, if $k = 8$
 - then: $A_{2c} + B_{2c} = A_b + B_b = (A+B)_{2c} = 10010010!!!$

CY	sign	useful digits	remark
0	0	1011010	A_b (90)
0	0	0111000	B_b (56)
0	1	0010010	sum (-18)

- the result is wrong, but $CY = 0!$ solution: e.g: OV – overflow bit is 1, if the result is not in the range: $-128 \dots 127$
 - eg. in this case $10010010 = 146$ in denary numeral system

Binary Operations

- Case 2:
 - $A > 0$ and $B < 0$ and $|A| > |B|$
 - in this case: $A_{2c} = A_b$ and $B_{2c} = 256 - B_b$, if $k=8$
 - then: $A_{2c} + B_{2c} = A_b + 256 - B_b = (A_b - B_b) + 256$
 - considering, that $(A_b - B_b) > 0$, there is an unnecessary bit – carry – in the result

- Case 2, e.g:
 - $A = 17, B = -9, k = 8$
 - in this case: $A_{2c} = A_b = 00010001$ and $B_{2c} = 256 - B_b = 11110111$, if $k=8$
 - then: $A_{2c} + B_{2c} = (A_b - B_b)_{2c} + 256 \equiv 8 = 100001000$ with an unnecessary bit

Binary Operations

CY	sign	useful digits	remarks
0	0	0010001	$A_b (17)$
0	1	1110111	$B_{2c} (-9)$
1	0	0001000	sum (8)

- the result is good, but CY=1, that is the unnecessary bit!

Binary Operations

- Case 3:
 - $A < 0$ and $B > 0$ and $|A| > |B|$
 - in this case: $A_{2c} = 256 - A_b$ and $B_{2c} = B_b$, if $k=8$
 - then: $A_{2c} + B_{2c} = 256 - A_b + B_b = 256 - (A_b - B_b)$ considering, that $(A_b - B_b) > 0$, the result will be a negative number in 2's complement code!

- Case 3, e.g:
 - $A = -17, B = 9, k = 8$
 - in this case: $A_{2c} = 256 - A_b = 11101111$ and $B_{2c} = B_b = 00001001$, if $k=8$
 - then: $A_{2c} + B_{2c} = (A_b - B_b)_{2c} + 256 \equiv -8 = 11111000$
 - the result is good, because the 2's complement code of $-8 = 256 - 8 = 11111000$

Binary Operations

CY	sign	useful digits	remarks
0	1	1101111	$A_b (-17)$
0	0	0001001	$B_{2c} (9)$
0	1	1111000	sum (-8)

- the result is good, the signed bit =1!

Binary Operations

- Case 4:
 - $A < 0$ and $B < 0$ and $|A| > |B|$
 - in this case: $A_{2c} = 256 - A_b$ and $B_{2c} = 256 - B_b$, if $k=8$
 - then: $A_{2c} + B_{2c} = 256 - A_b + 256 - B_b = 256 - (A_b + B_b) + 256$ considering, that $(A_b - B_b) > 0$, the result will be a negative number in 2's complement code, and also will be in the result an unnecessary bit!

- Case 4, e.g:
 - $A = -17, B = -9, k=8$
 - in this case: $A_{2c} = 256 - A_b = 11101111$ and $B_{2c} = 256 - B_b = 11110111$, if $k=8$
 - then: $A_{2c} + B_{2c} = (A_b - B_b)_{2c} + 256 \equiv -26 = 111100110$ with an unnecessary bit
 - the result is good, because the 2's complement code of $-26 = 256 - 8 = 11100110$

Binary Operations

CY	sign	useful digits	remarks
0	1	1101111	$A_{2c} (-17)$
0	1	1110111	$B_{2c} (-9)$
1	1	1100110	sum(-26)

- the result is good, the signed bit =1!, but CY=1, that is the unnecessary bit!

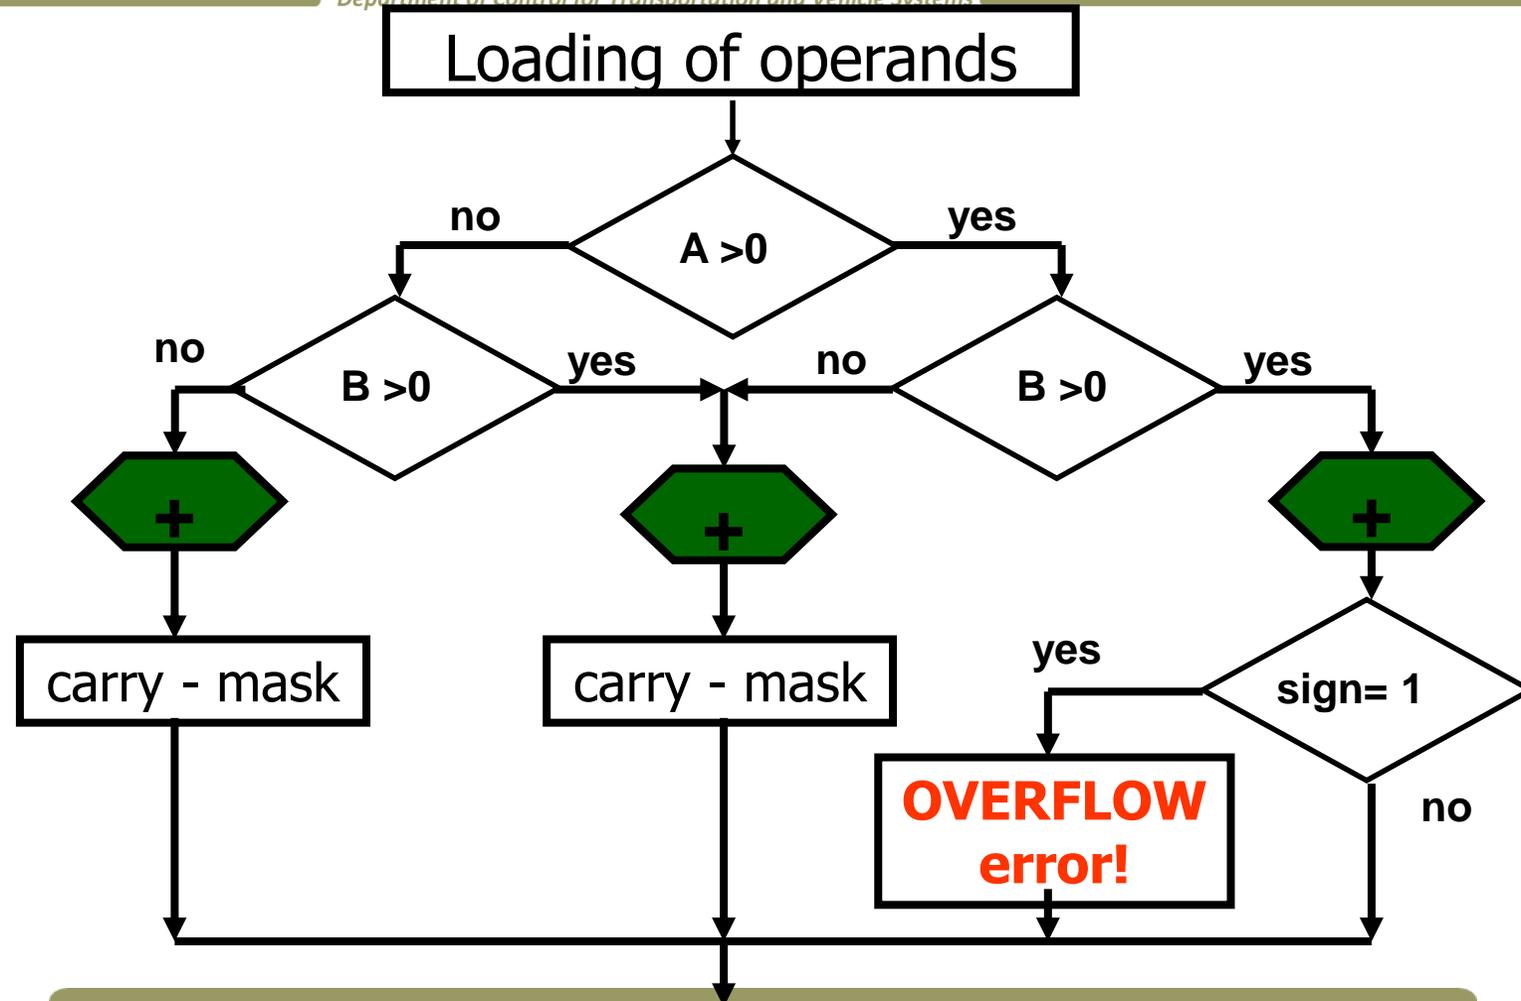

Binary Operations

- Summary of addition (subtraction) in 2's complement code:

Case	A	B	Carry	Remark
1	>0	>0	-	Result is good, (sign= 0)
2	>0	<0	exist	CY, result is good
3	<0	>0	-	Result is good (in 2'c)
4	<0	<0	exist	CY, (result in 2'c)

Binary Operations

- Logical scheme of a binary adder (e.g. in an ALU):

Binary Operations

- Fractional numbers in 2's complement code:

$$N_{2c} = \begin{cases} N, & \text{if } 1 > N \geq 0 \\ 2 - |N|, & \text{if } -1 < N < 0 \end{cases}$$

- e.g:

- $N = -0.75$

- in binary form: $-0.75_{10} = -0.11_2$

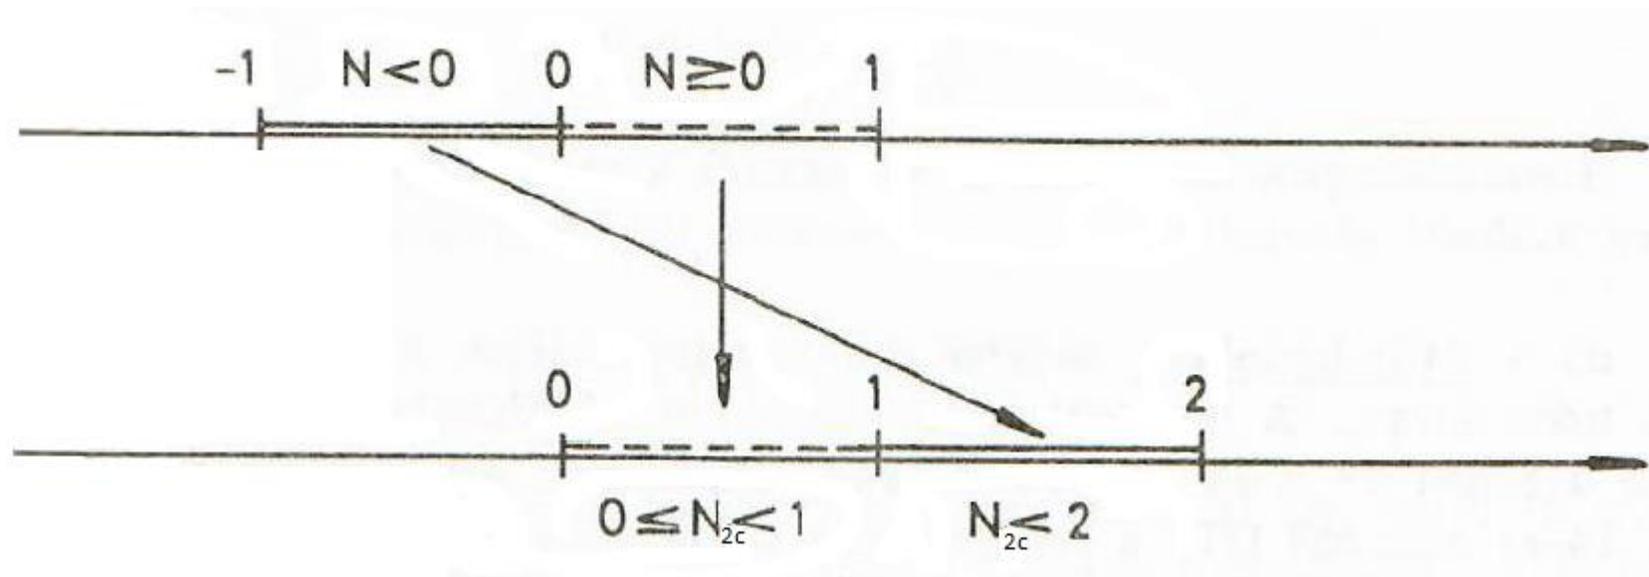

- $2_{10} = 10_2$, then:

2^1	2^0	2^{-1}	2^{-2}	2^{-3}	
1	0.	0	0	0	(2)
-	0.	1	1	0	(- N)
	1.	0	1	0	(N _{2c})

- the signed bit is the bit located at the local value 2^0

Binary Operations

- Fractional numbers in 2's complement code:
 - with other words, it is a transformation, shown on the next picture, if the fractional number is: between $-1 \dots 1$

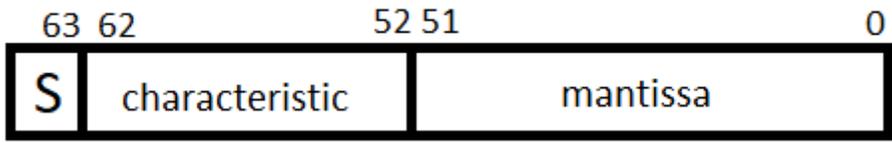

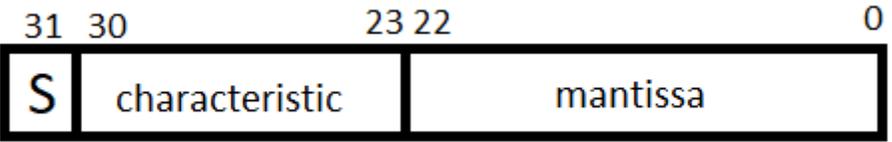

- not used in computer technology...

Binary Encoding

- Floating-point arithmetic – standard IEEE 754 -1985, nowadays: ISO/IEC/IEEE 60559:2011:

- $A = \pm m * 2^{\pm k}$, - every number can be written in this form,
- two main types are (other types also exist):
 - single-precision floating-point number – number representation in 32 digits, called also binary32
 - double-precision floating-point number – number representation in 64 digits, called also binary64

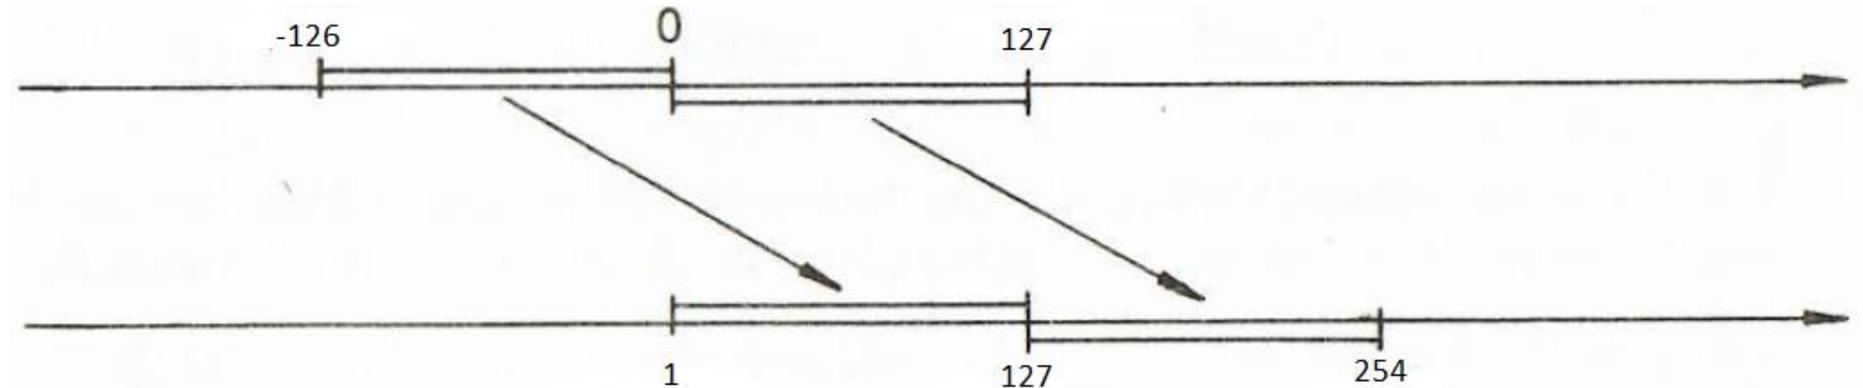

- signed bit:
 - 0, if the number is positive
 - 1, if the number is negative

Binary Encoding

- characteristic – single-precision:

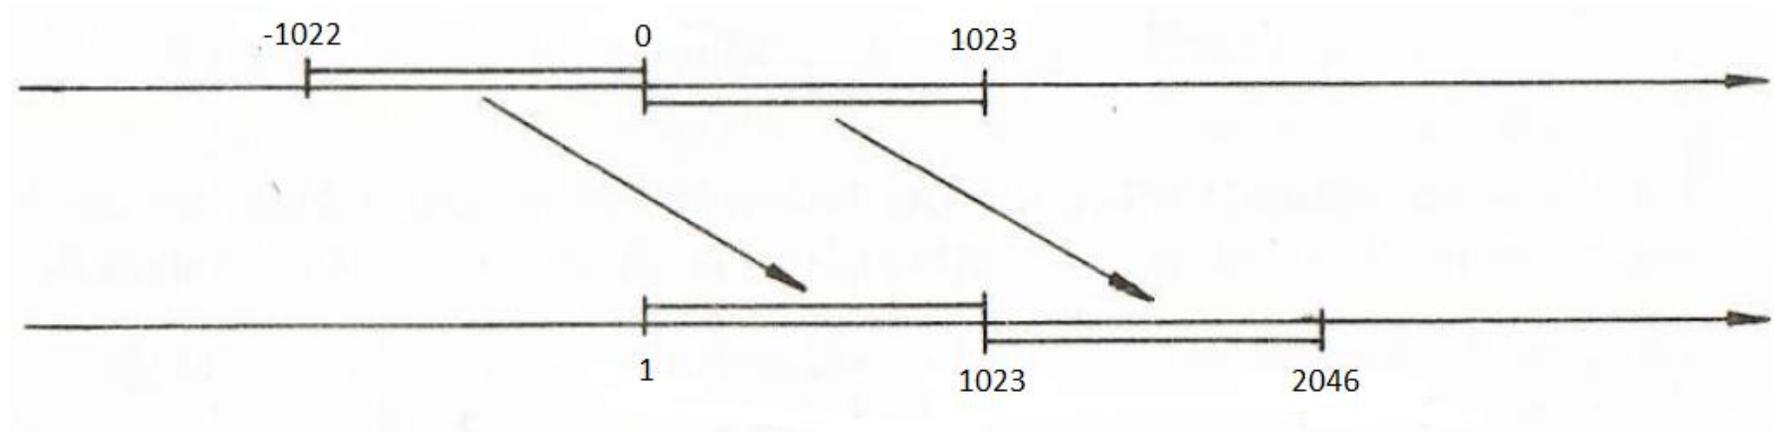

- $-2^{-7} + 2 \leq k < 2^7 - 1$
- $-126 \leq k < 127$ offset zero-point representation:
- $-126 = 00000001$
- $-125 = 00000010$
- $-124 = 00000011$
- ...
- $0 = 01111111$
- $1 = 10000000$
- $2 = 10000010$
- ...
- $127 = 11111110$

Binary Encoding

- characteristic – double-precision:

- $-2^{10} + 2 \leq k < 2^{10} - 1$
- $-1022 \leq k < 1023$ offset zero-point representation:
- $-1022 = 0000000001$
- $-1021 = 0000000010$
- $-1020 = 0000000011$
- ...
- $0 = 0111111111$
- $1 = 1000000000$
- $2 = 1000000001$
- ...
- $1023 = 1111111110$

Binary Encoding

- range of floating-point numbers:
 - single precision floating point numbers: $-(1 - 2^{-23}) * 2^{127} \leq N \leq (1 - 2^{-23}) * 2^{127}$
 - double precision floating point numbers: $-(1 - 2^{-52}) * 2^{1023} \leq N \leq (1 - 2^{-52}) * 2^{1023}$
 - $N_{max} \approx 2^{1023} \approx 9 * 10^{307}$
- precision of floating-point numbers:
 - single precision floating point numbers: $2^{-23} * 2^{127} = 2^{104}$
 - double precision floating point numbers: $2^{-52} * 2^{1023} = 2^{971}$
 - conversion from denary numeral system to floating-point arithmetic:
 1. convert to binary form,
 2. convert to normalized binary form,
 3. calculation of the characteristic,
 4. writing in the single/double precision floating point representation

Binary Encoding

- conversion from denary numeral system to single precision floating-point representation, e.g:

1. convert to binary form,

- by using the division and multiplication algorithms:
- $635,015625_{10} = 1001111011,000001_2$

2. convert to normalized binary form,

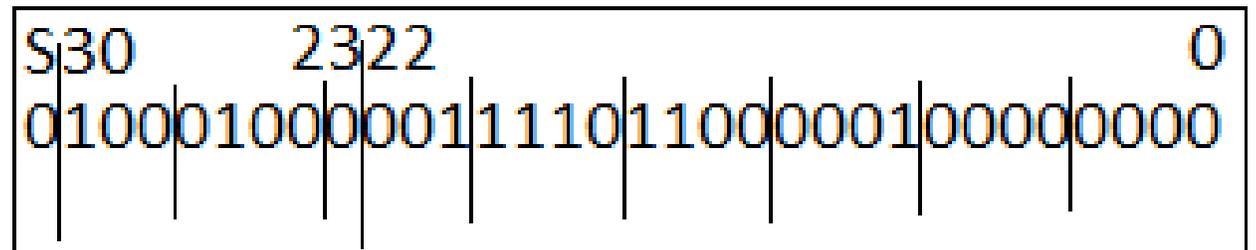

- $= 1001111011,000001 = 1001111011,000001 * 2^0$
- $= 1001111011,000001 * 2^0 = 1,001111011000001 * 2^9$

3. calculation of the characteristic,

- by using the offset zero point representation, $c = 127 + k = 127 + 9 = 136$
- $136_{10} = 10001000_2$ by using the division algorithm

4. writing in the single precision representation

- in binary fom:
- in hexadecimal form: 441EC100
